Fynd AMM ETH/USDG: LP net markout vs Binance, Oct 6 – Nov 5, 2026

Pool: Ekubo Core `0x0000…bd701` on Robinhood Chain, ETH/USDG, Fynd extension `0x550CFe12…1D09`. 30.2 days. Charts on pages 2 and 3; data and code in the attached zip.

Summary

- **LP net markout** = fees minus what LPs lost on each swap, valued at Binance 12 s later. It is the trading side of LP returns, **not position P&L or return on capital**.
- Over 20,326 swaps and $4.13M: fees $1,499 (3.63 bp), loss $4,694 (–11.37 bp), net **–$3,196 (–7.74 bp)**.
- One wallet I believe is Fynd's bot (not confirmed) is 80% of volume and –$2,699 of the net. It pays 1.36 bp in fees; external flow pays 12.95 bp. External flow nets –$496 (–6.13 bp).
- 92% of the loss is already there at the moment of the trade: the pool's price was behind Binance before the swap. 99% of volume moved the pool toward Binance across a gap bigger than its fee.

Results

Flow	Swaps	Volume	Fees	Loss at 12 s	LP net markout
All	20,326	$4.13M	$1,499 (3.63 bp)	–$4,694 (–11.37 bp)	**–$3,196 (–7.74 bp)**
Likely Fynd bot	17,146	$3.32M	$450 (1.36 bp)	–$3,149 (–9.49 bp)	**–$2,699 (–8.14 bp)**
External	3,180	$0.81M	$1,049 (12.95 bp)	–$1,545 (–19.08 bp)	**–$496 (–6.13 bp)**
External, toward Binance, gap > fee	2,664	$759k	$1,029 (13.57 bp)	–$1,545 (–20.36 bp)	–$515 (–6.79 bp)
External, other	516	$51k	$20 (3.84 bp)	–$0.46 (–0.09 bp)	+$19 (+3.75 bp)

bp = per dollar of swap volume. Measured loss is 0.58× theoretical LVR ($8,041). Figure 1 shows where the loss goes; Figure 2 shows a fee sweep, LVR by week and daily TVL.

Method

- Swaps from Ekubo Core logs; daily volume within 0.2% of GeckoTerminal. Binance ETHUSDC 1 s close before the block.
- Fees from the extension's FeesAccumulated events. Each pays in at the pool's next interaction, so it is split by size over the swaps since the previous event. On events covering a single swap, the bot pays 1.76 bp and external 13.28 bp.
- 68 swaps excluded (listed in the zip). 15 tests pass, including one swap recomputed by hand to the cent.
- Code written with AI assistance; I reviewed the outputs and hand-checked one swap end to end.

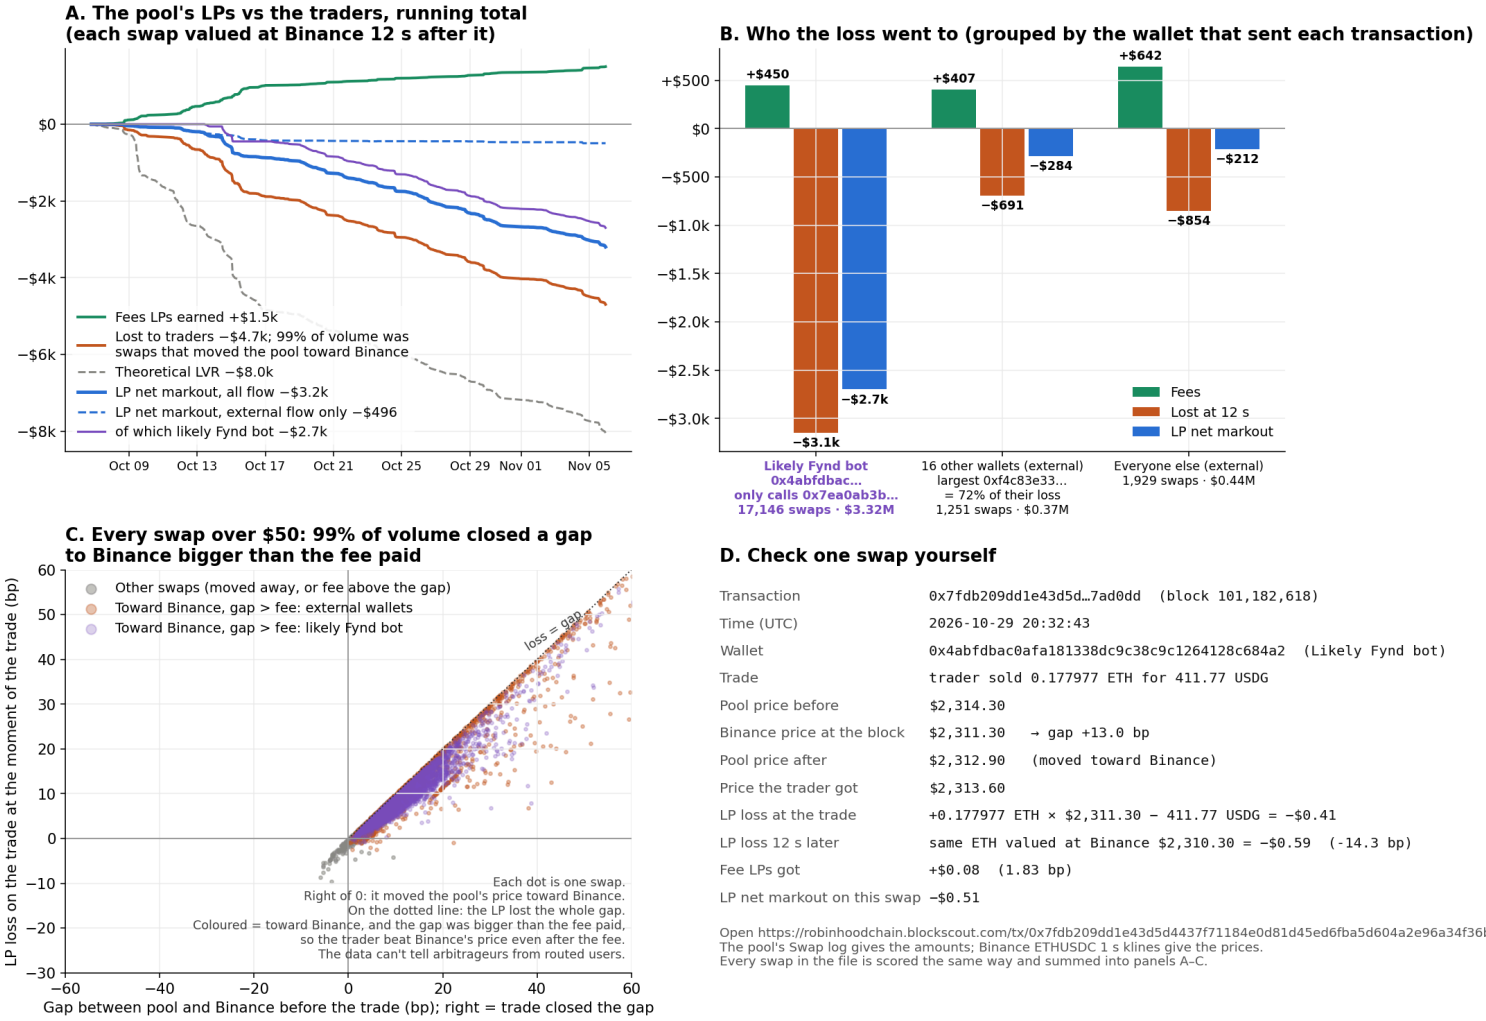

What the data can't show

- Who controls any wallet, or whether a swap was an arbitrageur or a routed user.
- Why the pool lags Binance, or why measured loss sits below theoretical LVR.
- Position P&L for any LP, or what a different fee would do once traders and routers respond.

Open questions

- Is `0x4abfdbac0afa181338dc9c38c9c1264128c684a2` your bot? All its 17,146 swaps go through `0x7ea0ab3b`.
- Fees are what the extension paid into the pool; LP positions have collected 91–96% of them, the rest is still in open positions. If Fynd takes an owner fee, I assume it comes off before this. Is that right?
- TVL rebuilt from events ($12,370 on Nov 8) doesn't yet match GeckoTerminal ($10,490 on Nov 9).
- Next, if useful: position-level LP return vs holding, and a comparison with Uniswap's USDG/WETH 0.01% pool.

Fynd AMM ETH/USDG (Ekubo, Robinhood), 30 days: LPs earned +$1.5k in fees and lost −$4.7k to traders; 99% of volume was swaps that moved the pool toward Binance External flow only (likely Fynd bot removed): fees +$1.0k, lost −$1.5k, LP −$496 (-6.1 bp of $0.81M)

Transaction	`0x7fdb209dd1e43d5d…7ad0dd  (block 101,182,618)`
Time (UTC)	`2026-10-29 20:32:43`
Wallet	`0x4abfdbac0afa181338dc9c38c9c1264128c684a2  (Likely Fynd bot)`
Trade	`trader sold 0.177977 ETH for 411.77 USDG`
Pool price before	`$2,314.30`
Binance price at the block	`$2,311.30  → gap +13.0 bp`
Pool price after	`$2,312.90  (moved toward Binance)`
Price the trader got	`$2,313.60`
LP loss at the trade	`+0.177977 ETH × $2,311.30 − 411.77 USDG = −$0.41`
LP loss 12 s later	`same ETH valued at Binance $2,310.30 = −$0.59  (-14.3 bp)`
Fee LPs got	`+$0.08  (1.83 bp)`
LP net markout on this swap	`−$0.51`

The pool's Swap log gives the amounts; Binance ETHUSDC 1 s klines give the prices.
Every swap in the file is scored the same way and summed into panels A–C.

20,326 swaps, $4.13M volume, 2026-10-06 – 2026-11-05. Loss = LP's token change valued at Binance ETH/USDC (USDG = $1; last 1 s close before the block's second), fees excluded. Fees are the extension's FeesAccumulated events, which pay in at the pool's next interaction: each is split over the swaps since the previous one. Theoretical LVR = $\sigma^2 \cdot L \cdot \sqrt{S}/4$ per minute. Swaps more than 1% from Binance excluded (67, listed in _excluded.csv). Toward Binance, gap > fee: swaps that moved the pool toward Binance, from a gap bigger than the fee paid; the data can't tell arbitrageurs from routed users. Likely Fynd bot = 0x4abfdbac0afa181338dc9c38c9c1264128c684a2, listed in INTERNAL_WALLETS in flow_classify.py by us, not by Fynd: it sent every one of its 17,146 swaps through 0x7ea0ab3b. Not confirmed by the Fynd team.

Figure 1. Where the LP loss comes from: running totals (A), by wallet group (B), gap vs loss for every swap (C), and one swap worked through by hand (D).

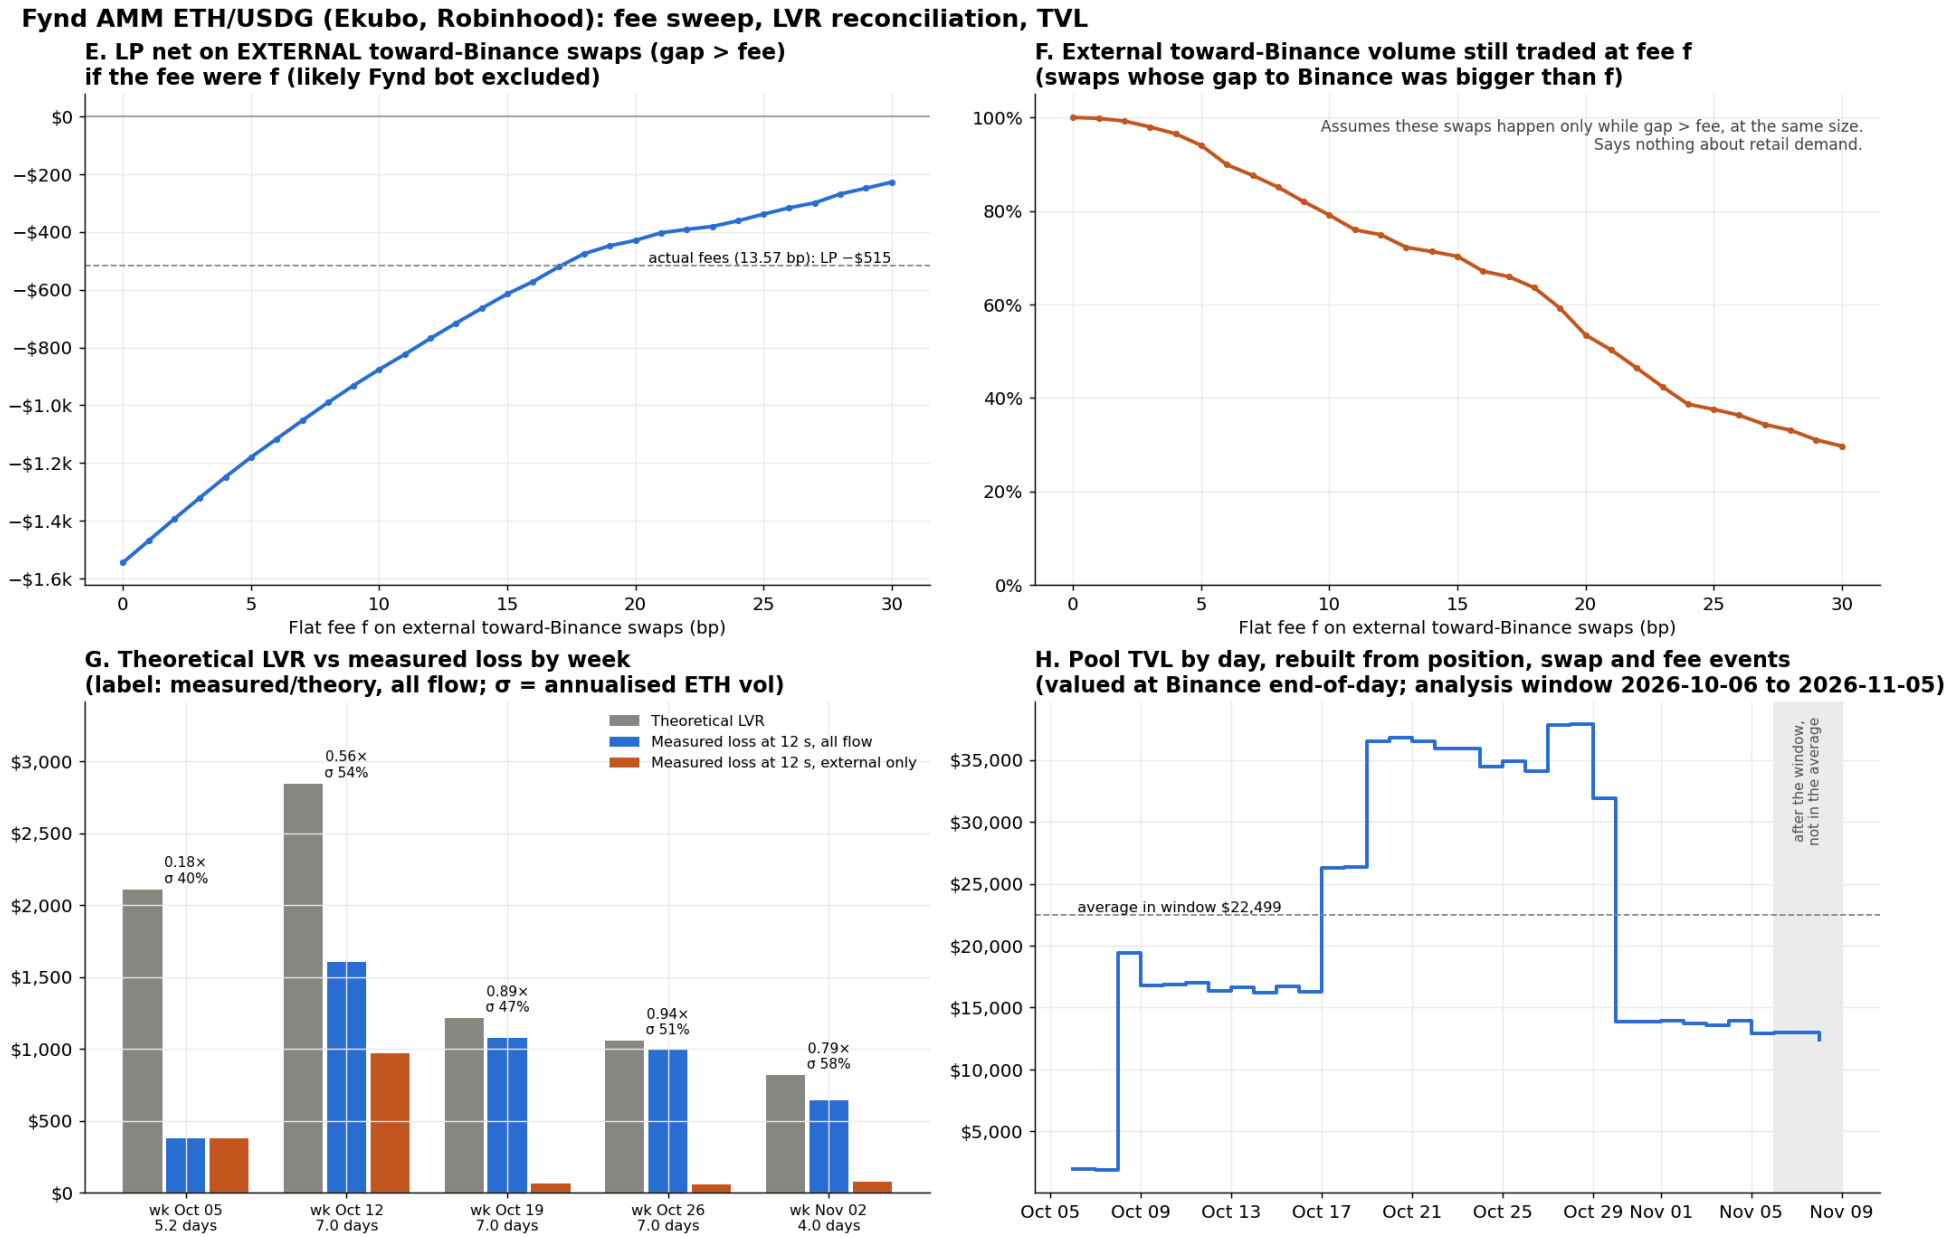

Figure 2. Fee sweep on external toward-Binance swaps (E, F), theoretical LVR vs measured loss by week (G), and daily TVL rebuilt from events (H). The sweep can't reach zero by construction (each kept swap loses about its gap and pays less); it is a bound, not a fee recommendation.
