Fynd AMM ETH/USDG: LP returns vs holding, Oct 2 – Nov 11, 2026

Revised Nov 11 after your note on bot capture. Every LP position since the pool started: 174 positions, 8 LPs, to block 111,478,410 (Nov 11, 05:53 UTC). Follows the Nov 10 markout report. Chart on page 2; data and code in the attached zip.

Summary

- **LP vs holding** = what each position ended with (withdrawals, fees, and what it still holds) minus the tokens it deposited, both valued at the same ETH price. ETH's own price move is the same on both sides and drops out.
- Against holding, LPs are **–$3,690** on $18,672 average capital: fees +$1,948, impermanent loss –$5,638. That is **–$148 per $1,000 of capital per 30 days (–14.8%)**.
- The main LP (`0x6c6a…7127`, 57% of capital, ranges ~1.6% wide, median position open about an hour) earns the most fees and loses the most: +$126 / –$342 / net –$217 per $1,000 per 30 days. The other 7 LPs, with ranges ~16% wide: +$17 / –$76 / net –$59. Narrow ranges scale fees and losses up together; in both groups losses outran fees.
- **Most of the loss is the pool lagging the market, not what traders capture.** Split swap by swap: fees +$1,961 (valued when paid); traders' capture, valued at the price each trade left the pool at, –$1,416; the pool still behind Binance after the trade –$3,652; price moves after trades –$583. Per $1,000 per 30 days: capture –$57 (95%: –$79 to –$46), pool lag –$147 (95%: –$200 to –$124).
- **Your bot captures little:** $757 (1.94 bp) at the prices it leaves the pool at, against $539 (1.38 bp) in fees it pays, so +$218 over 35 days before its costs elsewhere. But it moves the pool toward a price ~15 s old: the median gap to Binance is 8.3 bp before its trade and 5.4 bp after, on the same side 99% of the time. That lag, not the bot's take, is where LPs lose.
- 7 of 8 LPs did worse than holding (the eighth: +$1.90 on $95). Matches the Nov 10 markout report: –$3,108 vs –$3,196 over its window.

Results

LPs	Positions	Avg capital	Fees	Impermanent loss	LP vs hold	Per $1,000 / 30 d	LP $ result	Hold $ result
Main LP `0x6c6a…7127`	150	$10,556	+$1,766	–$4,813	**–$3,047**	–$217	–$4,175	–$1,129
Other 7 LPs	24	$8,116	+$182	–$825	**–$643**	–$59	–$1,821	–$1,178
All	174	$18,672	+$1,948	–$5,638	**–$3,690**	–$148	–$5,997	–$2,307

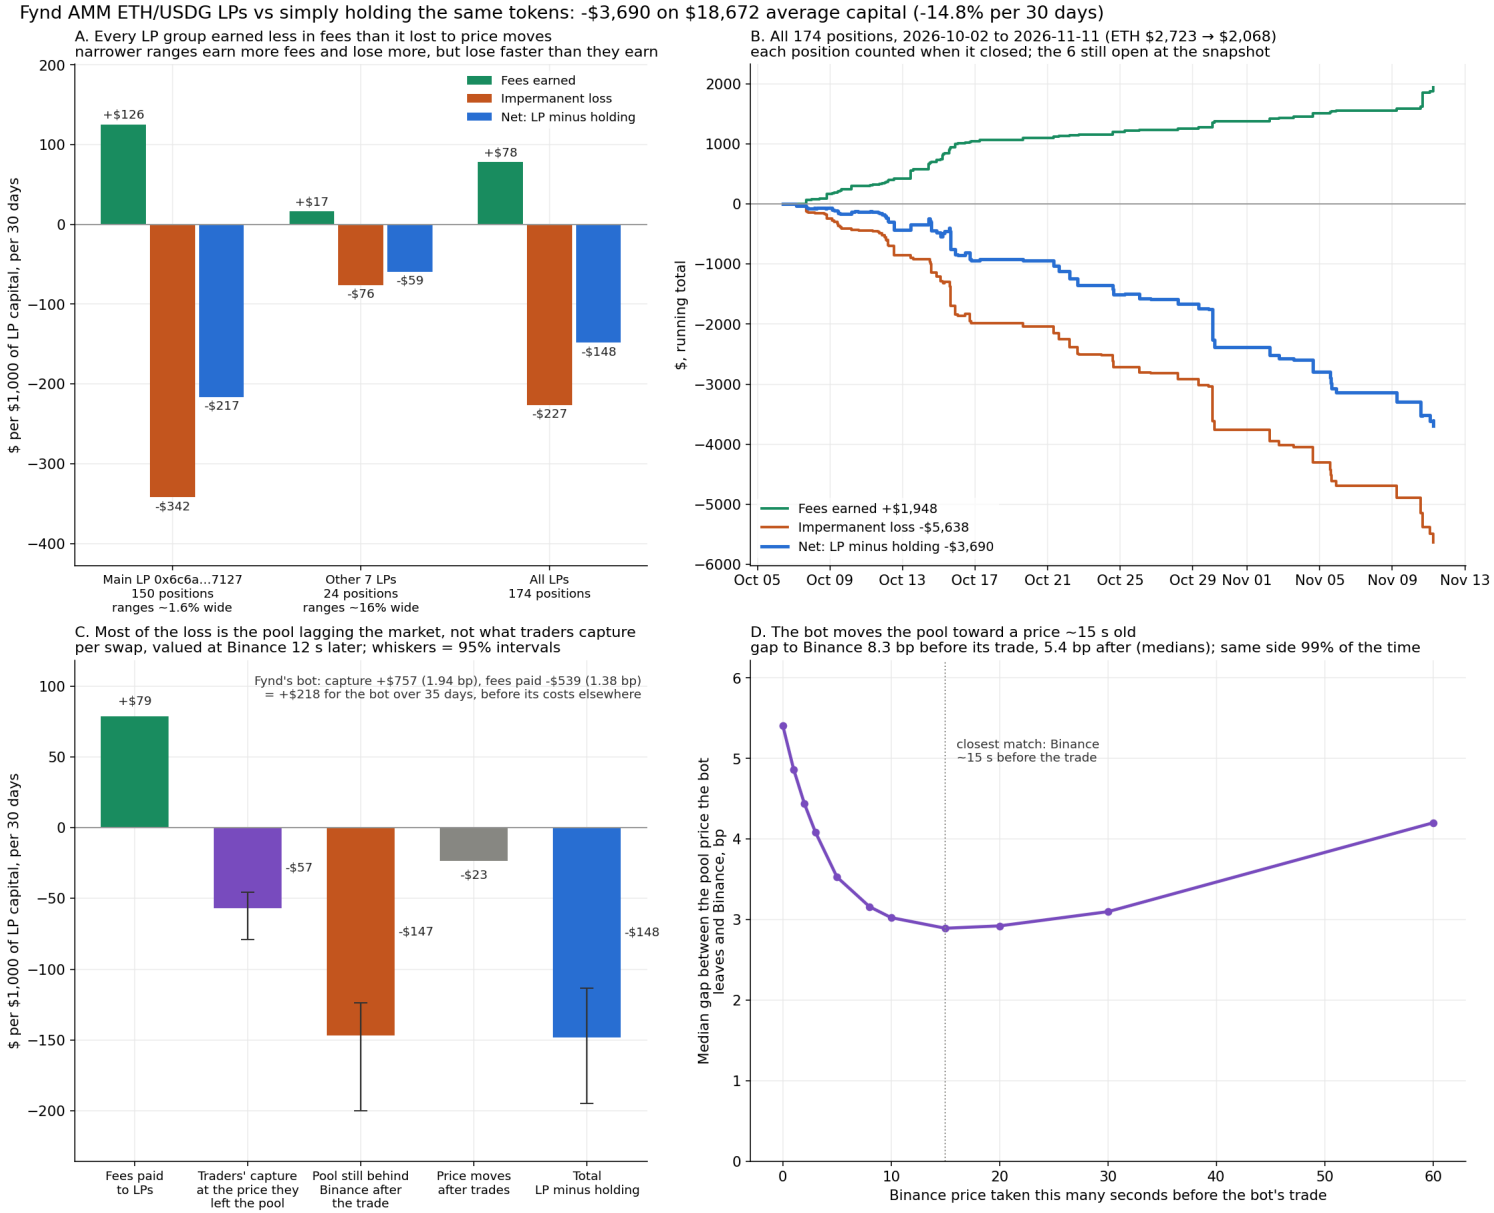

Valued at Binance ETHUSDC at each position's end (last withdrawal, or the snapshot if still open). Capital = cost of deposits × days held. The $ results include ETH's 24% fall ($2,723 → $2,068), which holding suffers too. Per-LP and per-position rows are in the zip.

Checks

- **The books close.** What the open positions hold on chain (2.841752 ETH, 9,103.62 USDG) equals every deposit, withdrawal, fee and swap since the pool started, added up.
- **Every fee paid in reached LP positions** (100.000% of ETH and USDG, collected or uncollected). So any owner fee comes off before `FeesAccumulated`, not from LPs afterwards.
- 176 deposits match liquidity × pool price within 0.05%. One position recomputed by hand from raw events and the raw Binance file. The split adds back to LP vs holding exactly. 22 tests pass.
- **TVL:** ours is ~15% above GeckoTerminal ($14,966 vs $12,795 today). Without the one out-of-range position it is $13,274, so GeckoTerminal may not count out-of-range liquidity. Not confirmed.

What the data can't show

- Hedging costs. An LP that shorts the ETH it deposits ends with LP vs holding, before hedge costs: hedging removes ETH's move, not impermanent loss. So these figures already are the hedged result.
- The bot's P&L outside the pool. Anything beyond this 40-day period; "per 30 days" is not an APR.
- How a Uniswap LP did on the same pair and days. That comparison is next.
- **What price does the bot target, and how does it hedge?** If it hedges at Binance-like prices, it books part of the lag; if not, the lag is a pure cost of the pool trailing the market. And is `0x6c6a40d2d1fc442e281e1f80314fd86516e17127` yours?

LP = what each position paid out (withdrawals + fees collected) plus what it still holds; holding = the tokens it deposited. Both valued at Binance ETHUSDC at the position's end, so ETH's own price move cancels.
Impermanent loss = tokens out minus tokens in at that price, before fees. Capital = cost of deposits x days held. Snapshot block 111,478,410. Books close: the open positions on chain hold exactly what all deposits, withdrawals, fees and swaps add up to.

Figure. A: fees, impermanent loss and LP vs holding per $1,000 of capital per 30 days, by LP group. B: running totals, each position counted when it closed. C: where LP vs holding comes from, with 95% intervals. D: how stale the price is that the bot moves the pool to.
